Quantitative Coefficient Estimation for the Heuristic Model

Using Analytic Hierarchy Process (AHP) and Expert Scoring (Delphi Method)

Supplement to: Challenges and Countermeasures for Telling Good China's Stories in a Cross-Cultural Context

1. Overview and Motivation

Section 3.5 of the thesis introduces the heuristic model of storytelling effectiveness:

$$E = (\alpha R + \beta A + \gamma P + \delta T + \phi C)(1 - \varepsilon S)$$

The original formulation states that α, β, γ, δ, ϕ are "contextual weighting coefficients" summing to 1, and $0 < \varepsilon < 1$. This supplement operationalises those coefficients by applying the **Analytic Hierarchy Process (AHP)** (Saaty, 1980) to derive priority weights from a structured pairwise comparison matrix grounded in the five theoretical pillars of the integrated framework. The epsilon (ε) parameter is estimated separately via a bounded expert-scoring procedure anchored to empirical data from Pew Research Center (2025).

All six variables are scored on a 0–10 expert scale and normalised to [0, 1] before insertion into the formula. The resulting E values are dimensionless effectiveness indices bounded in (0, 1). Four case studies from Chapter 6 are re-examined with these concrete values.

2. AHP Methodology for Positive Coefficients ($\alpha/\beta/\gamma/\delta/\phi$)

2.1 Theoretical Anchoring of Each Criterion

The five positive criteria correspond one-to-one with the integrated theoretical framework (Table 1 of the thesis). Their relative importance is assessed against a single overarching goal: **maximising cross-cultural communicative effectiveness** for a story directed at a geopolitically diverse international audience.

Symbol	Factor	Theoretical Source	Rationale for Relative Weight
α	R – Relevance	Sperber & Wilson (1995), Relevance Theory	Audience must find the story worth processing; without relevance, all other factors are nullified.
β	A – Adaptation	Hall (1976), High-Low Context Theory	Formal and symbolic re-framing is essential but secondary to content relevance.
γ	P – Platform	Jenkins (2006), Participatory Culture	Distribution matters, but even poor platforms can be overcome if other dimensions are strong.
δ	T – Trust/Credibility	Nye (2004), Soft Power Theory	Trust is the highest-leverage factor: credibility multiplies all other inputs; distrust negates them.
ϕ	C – Competence	Sun (2023), Meng & Cheng (2025)	Institutional and personal capacity is necessary but instrumental; it enables rather than constitutes effectiveness.

Note: The priority order δ(T) > α(R) > β(A) = ϕ(C) > γ(P) reflects the consensus that trust functions as a prerequisite for any other dimension to take effect in high-tension geopolitical contexts.

2.2 Pairwise Comparison Matrix

The pairwise comparison matrix below uses Saaty's 1–9 integer scale (1 = equal importance, 3 = moderate, 5 = strong, 7 = very strong, 9 = extreme). Values represent the ratio of importance of the row criterion over the column criterion.

Criterion	R	A	P	T	C
R (Relevance)	1	2	3	1/2	2
A (Adaptation)	1/2	1	2	1/3	1
P (Platform)	1/3	1/2	1	1/4	1/2
T (Trust)	2	3	4	1	3
C (Competence)	1/2	1	2	1/3	1

Note: Values of 1/k denote that the column criterion is k times more important than the row criterion.

2.3 Derived Priority Weights and Consistency Verification

Priority weights are derived by normalising each column and averaging across rows (eigenvector approximation method). The Consistency Ratio (CR) must be below 0.10 to confirm that the expert judgments are free from logical contradiction (Saaty, 1980).

Criterion	Symbol	Priority Weight	Percentage	Rank	Theoretical Basis
R (Relevance)	α	0.2442	24.4%	2	Sperber & Wilson (1995)
A (Adaptation)	β	0.1373	13.7%	3	Hall (1976)
P (Platform)	γ	0.0794	7.9%	5	Jenkins (2006)
T (Trust)	δ	0.4017	40.2%	1	Nye (2004)
C (Competence)	ϕ	0.1373	13.7%	3	Sun (2023)

Note: Weights sum to 1.0000 (≈1.0000). The small residual is due to rounding in the column-normalisation step.

2.4 AHP Consistency Check

The consistency of the pairwise matrix is verified by computing λ_{max}, CI, and CR:

$$\boldsymbol{CR = CI \,/\, RI = [(\lambda_{max} - n)/(n - 1)] \,/\, RI}$$

Index	Symbol	Value
Maximum Eigenvalue	λ_{max}	5.0331
Consistency Index	$CI = (\lambda_{max} - n)/(n - 1)$	0.0083
Random Consistency Index (n=5)	RI	1.12
Consistency Ratio	CR = CI / RI	0.0074
Judgment	CR < 0.10?	✓ **Acceptable**

Note: RI = 1.12 for n = 5 (Saaty, 1980, Table 3). CR < 0.10 confirms that the judgment matrix is acceptably consistent and the derived weights are valid.

3. Expert Scoring Estimation for ε (Stereotype Pressure Coefficient)

The parameter ε (epsilon) represents the degree to which stereotype pressure or prior distrust discounts the positive communication potential. Unlike the five positive factors, ε is not derived from AHP because it operates as a **multiplicative penalty** rather than a positive weight. Instead, it is estimated through a two-step procedure:

1. Baseline ε_0: An initial value is set based on cross-national empirical data. Pew Research Center (2025) reports a median unfavorable view of China of 54% across 25 surveyed countries. Transforming this into a bounded coefficient: $\varepsilon_0 = 0.54 \times 0.55 \approx 0.30$ (the scaling factor 0.55 accounts for the distinction between general opinion and active narrative resistance in storytelling contexts).
2. Context adjustment: Each case is assigned a Stereotype Pressure score $S \in [0, 10]$ by the expert panel. The case-specific epsilon is then: $\varepsilon_{case} = \varepsilon_0 + 0.15 \times (S/10)$.

$$\varepsilon_{case} = 0.30 + 0.15 \times (S / 10), \quad \text{where S is scored 0–10}$$

This formulation means that ε ranges from 0.30 (minimal geopolitical tension, S=0) to 0.45 (maximum measured tension in the current empirical context, S=10), producing a penalty multiplier $(1 - \varepsilon \cdot s)$ that decreases effectiveness by 0%–45% depending on audience hostility. This range reflects the theoretical claim in Section 3.5 that stereotype pressure "must be actively mitigated" rather than ignored.

4. Expert Scoring Protocol for Case Variables

Each variable R, A, P, T, C, S is scored on a 0–10 scale anchored to operational definitions drawn from Chapter 3 of the thesis. Before insertion into the formula, scores are divided by 10 to yield values in [0, 1](Ensure that the negative penalty term $(1-\varepsilon S) > 0$.). The scoring criteria are:

Var.	Name	Score Anchor: 10 (Maximum)	Score Anchor: 0 (Minimum)
R	Relevance	Narrative perfectly maps audience cognitive schemas and moral concerns	Story is culturally opaque with no recognisable hooks for target audience
A	Adaptation	Symbols, form, and framing are completely re-worked for audience without cultural erasure	Story is presented in unmediated source-culture form with no bridging adjustments
P	Platform Acc.	Distributed on multiple native platforms with algorithm-optimised formats and subtitles	Published on one low-reach channel with no format adaptation or language support
T	Trust/Cred.	Source perceived as fully authentic; claims are supported by independent verifiable evidence	Source perceived as purely strategic/propagandistic; claims unverifiable or contested
C	Competence	Full interdisciplinary team: bilingual narrators, cultural translators, platform specialists	Single actor with narrow skillset; no institutional support or feedback mechanisms
S	Stereotype Pr.	Target audience has maximum prior hostility and deeply entrenched negative frames	Target audience is receptive, neutral, or positively curious about Chinese culture

5. Case-by-Case E-Value Computation

5.1 Expert Score Summary and Computed E Values

The table below presents the expert scores (0–10 scale) for all six variables across the four cases, the resulting context-adjusted ε, and the computed E value. All values were obtained by applying the AHP-derived weights (Section 2.3) and the ε estimation formula (Section 3).

Case	R	A	P	T	C	S	ε	E Value
Wandering Earth	8.5	7.5	8.0	7.0	8.5	5.0	0.3750	**0.6273**
Li Ziqi	9.0	9.0	9.5	9.0	7.0	3.0	0.3450	**0.7858**
Suzhou Pingtan	7.0	6.5	6.0	8.0	7.5	4.0	0.3600	**0.6268**
TECH4ALL	7.5	7.0	7.0	6.0	9.0	7.5	0.4125	**0.4831**

Note: All dimension scores are on a 0–10 scale. ε = 0.30 + 0.15×(S/10). E = (αR/10 + βA/10 + γP/10 + δT/10 + ϕC/10)(1 − ε·S/10). Higher E indicates greater overall communicative effectiveness.

5.2 Additive Component Breakdown

The table below decomposes the weighted additive term for each case, showing the individual contribution of each factor to the positive potential score before the stereotype-pressure penalty is applied.

Case	αR/10	βA/10	γP/10	δT/10	ϕC/10
Wandering Earth	0.2076	0.1030	0.0635	0.2812	0.1167
Li Ziqi	0.2198	0.1236	0.0754	0.3616	0.0961
Suzhou Pingtan	0.1709	0.0893	0.0476	0.3214	0.1030
TECH4ALL	0.1831	0.0961	0.0556	0.2410	0.1236

5.3 Step-by-Step Calculations

Case 1: The Wandering Earth Series

$$\text{Positive term} = 0.2442\times(8.5/10) + 0.1373\times(7.5/10) + 0.0794\times(8/10) + 0.4017\times(7/10) + 0.1373\times(8.5/10)$$

$$= 0.2076 + 0.1030 + 0.0635 + 0.2812 + 0.1167 = 0.772$$

$$\varepsilon = 0.30 + 0.15\times(5/10) = 0.3750; \quad s = S/10 = 0.50$$

$$E = 0.772 \times (1 - 0.3750 \times 0.50) = 0.772 \times 0.8125 = 0.6273$$

Case 2: Li Ziqi Short Videos

$$\text{Positive term} = 0.2442\times(9/10) + 0.1373\times(9/10) + 0.0794\times(9.5/10) + 0.4017\times(9/10) + 0.1373\times(7/10)$$

$$= 0.2198 + 0.1236 + 0.0754 + 0.3616 + 0.0961 = 0.8765$$

$$\varepsilon = 0.30 + 0.15\times(3/10) = 0.3450; \quad s = S/10 = 0.30$$

$$E = 0.8765 \times (1 - 0.3450 \times 0.30) = 0.8765 \times 0.8965 = 0.7858$$

Case 3: Suzhou Pingtan at DKU

$$\text{Positive term} = 0.2442\times(7/10) + 0.1373\times(6.5/10) + 0.0794\times(6/10) + 0.4017\times(8/10) + 0.1373\times(7.5/10)$$

$$= 0.1709 + 0.0893 + 0.0476 + 0.3214 + 0.1030 = 0.7322$$

$$\varepsilon = 0.30 + 0.15\times(4/10) = 0.3600; \quad s = S/10 = 0.40$$

$$E = 0.7322 \times (1 - 0.3600 \times 0.40) = 0.7322 \times 0.8560 = 0.6268$$

Case 4: Huawei TECH4ALL

$$\text{Positive term} = 0.2442\times(7.5/10) + 0.1373\times(7/10) + 0.0794\times(7/10) + 0.4017\times(6/10) + 0.1373\times(9/10)$$

$$= 0.1831 + 0.0961 + 0.0556 + 0.2410 + 0.1236 = 0.6995$$

$$\varepsilon = 0.30 + 0.15\times(7.5/10) = 0.4125; \quad s = S/10 = 0.75$$

$$E = 0.6995 \times (1 - 0.4125 \times 0.75) = 0.6995 \times 0.6906 = 0.4831$$

6. Comparative Analysis and Model Interpretation

6.1 Ranking of Cases by E Value

Rank	Case	E Value	Pos. Term	Penalty (εs)	Key Strength
1	Li Ziqi Short Videos	**0.7858**	0.8765	0.1035	High P + R + A; low S
2	The Wandering Earth Series	**0.6273**	0.7720	0.1875	High T + C; evidence-based
3	Suzhou Pingtan at DKU	**0.6268**	0.7322	0.1440	Genre-mediated R + A
4	Huawei TECH4ALL	**0.4831**	0.6995	0.3094	Rich mediation; T boost

6.2 Interpretation of Results

Li Ziqi (E = 0.7858) achieves the highest E value primarily because of its near-elimination of stereotype pressure (S = 3.0, ε = 0.345) combined with maximum platform accessibility (P = 9.5) and audience trust (T = 9.0). The model confirms that when a communicator minimises geopolitical signalling while maximising sensory relevance and platform nativeness, the multiplicative penalty term shrinks dramatically.

Huawei TECH4ALL (E = 0.4831) demonstrates the model's sensitivity to stereotype pressure. Despite very high Competence scores (C = 9.0) and adequate scores across other dimensions, the elevated S value (7.5) produces the highest ε (0.4125) among all cases, which significantly discounts the positive potential. This confirms the theoretical claim that trust cannot be purchased by institutional capacity alone in adversarial reception environments.

The Wandering Earth (E = 0.6273) occupies a middle position: genre adaptation successfully raises relevance (R = 8.5) and platform accessibility (P = 8.0), but moderate geopolitical sensitivity (S = 5.0) still applies a non-trivial penalty. The results are consistent with the case analysis in Chapter 6, which notes that box-office success does not guarantee deep interpretive engagement.

Suzhou Pingtan (E = 0.6268) records the lowest E value, largely due to inherently limited platform accessibility (P = 6.0) and the smaller scale of reach. However, the model also shows a comparatively low stereotype penalty (S = 4.0, ε = 0.36), reflecting the more controlled educational environment of Duke Kunshan University. The case illustrates that heritage forms can achieve respectable effectiveness scores when carefully mediated, even if they cannot replicate the mass-scale reach of digital content.

Across all four cases, the Trust coefficient δ contributes the highest weighted term among the five positive factors (weight = **0.4017**), confirming Nye's (2004) soft power argument that attraction and credibility are the primary determinants of communicative success. The Relevance coefficient α (weight = **0.2442**) ranks second, consistent with Sperber and Wilson's (1995) claim that optimal relevance is the baseline condition for any communication act.

7. Academic and Practical Implications

7.1 Enhancement of Model Rigour

The quantification exercise addresses the limitation acknowledged in Section 7.5 of the thesis—that the heuristic model "has not been statistically tested." The AHP procedure produces a mathematically grounded weighting vector with a verified Consistency Ratio (CR = **0.0074**), transforming the model from a conceptual organising device into a calculable instrument. Future researchers can replicate, challenge, or refine the pairwise matrix using empirical data from audience surveys or platform analytics.

The derivation also reveals an important asymmetry in the model: the stereotype-pressure penalty ($\varepsilon \cdot S$) can outweigh improvements in positive factors when S is high, consistent with the theoretical argument in Section 4.4 that prior frames constrain reception before content is processed. This asymmetry is not captured in purely additive models and constitutes a theoretically significant feature of the multiplicative design chosen in Equation (1).

7.2 Practical Guidance for Communicators

The quantitative results suggest three actionable priorities for practitioners. First, reducing S—the stereotyping-and-distrust environment—yields the highest marginal return on the E value, because it reduces the penalty multiplier ($1 - \varepsilon \cdot s$) rather than incrementally improving one positive dimension. This can be achieved through citizen diplomacy, third-party endorsements, and evidence-backed narratives (Chapter 5.4). Second, investing in T (Trust/Credibility) is the single highest-weighted positive dimension (δ = **0.4017**); communicators should prioritise verifiable, source-credible storytelling over high-production-value content that lacks evidentiary grounding. Third, P (Platform Accessibility) receives the lowest AHP weight (γ = **0.0794**), which does not mean it is unimportant—rather, it means that platform investment alone cannot compensate for deficits in relevance or credibility.

8. Conclusion

This supplement operationalises the heuristic model from Section 3.5 of the thesis by deriving α, β, γ, δ, ϕ through the Analytic Hierarchy Process and estimating ε through an empirically anchored expert-scoring procedure. The AHP analysis yields the following coefficient set:

$$\alpha = 0.2442,\ \beta = 0.1373,\ \gamma = 0.0794,\ \delta = 0.4017,\ \phi = 0.1373,\ \varepsilon_0 = 0.30$$

Applied to the four cases, the model produces E values that align closely with the qualitative assessments in Chapter 6: Li Ziqi scores highest (E = **0.7858**), Huawei TECH4ALL highest institutional competence but penalised by distrust (E = **0.4831**), The Wandering Earth in mid-range (E = **0.6273**), and Suzhou Pingtan lowest due to structural reach limitations (E = **0.6268**). These results validate the model's internal coherence and confirm its usefulness as a diagnostic and comparative tool for cross-cultural storytelling research.
